

Rupture of the Membranes - Preterm Premature (PPROM)

Immediate Actions

- Admit to Birth Centre for assessment
- The diagnosis is usually made on clinical grounds
 - Perform a sterile speculum examination and perform Amnisure/Actim Prom
 - A digital vaginal examination should NOT be performed routinely
 - Ultrasound examination for presentation. Note- ultrasound of amniotic fluid volume may be helpful but is not diagnostic
- Administer antibiotics as per protocol, guided by gestational age
- Administer corticosteroids
- Plan ongoing management

1. Purpose

This clinical guideline outlines the requirement for the management of preterm premature rupture of the membranes (PPROM) at the Women's.

Where processes differ between campuses, those that refer to the Sandringham campus are differentiated by pink text or have the heading **Sandringham campus**.

Sandringham campus: Women with PPRM at 23 to 34 weeks gestation require transfer to the Women's or the most appropriate tertiary centre.

Risks associated with PPRM include:

- Preterm labour
- Cord prolapse
- Placental abruption
- Intrauterine infection/chorioamnionitis
- Pulmonary hypoplasia

This guideline is related to:

- Premature Rupture of Membranes at Term
- Prevention & Treatment of Early Onset GBS in Neonates

2. Definitions

Preterm Premature Rupture of the Membranes (PPROM) is the rupture of the membranes prior to 37 completed weeks gestation and prior to the onset of labour.

3. Responsibilities

Clinical staff caring for a woman with PPRM.

4. Guideline

Admit to Birth Centre.

4.1. *Diagnosis*

The diagnosis can usually be made on clinical grounds by a combination of history and the identification of amniotic fluid in the vagina on speculum examination.

- All women presenting with a history of PPRM must have a sterile speculum examination
- A digital vaginal examination should NOT be performed routinely

Rupture of the Membranes - Preterm Premature (PPROM)

- Ultrasound examination showing markedly reduced liquor volume in the presence of normal fetal kidneys and the absence of FGR is highly suggestive of ROM, however normal liquor volume does not exclude the diagnosis
- If the diagnosis is in doubt, the woman may be admitted for pad checks

4.2. Evaluation

- General examination including pulse and temperature
- Abdominal examination
- Sterile speculum examination
 - Confirm the diagnosis through identifying the presence of liquor (Amnisure/ **Actim Prom** may be considered)
 - Collect cervico-vaginal swabs for microscopy and culture
 - Collect low vaginal and ano-rectal swabs for GBS
 - Estimate cervical dilatation
 - Exclude cord prolapse
- CTG
- FBE
- Birth Centre ultrasound examination if presentation is in doubt
- Consider a formal ultrasound for fetal number, weight, presentation, morphology and liquor volume
- A cervical suture, if present, should be removed immediately and submitted for culture.

4.3. Prophylaxis for neonatal respiratory distress syndrome

All women with PPRM <34 weeks gestation should be administered corticosteroids betamethasone injection 11.4mg IM Daily - 2 doses, 24 hours apart (Celestone Chronodose™)

Sandringham campus: Administer the first dose prior to arranging transfer to the Women's or a tertiary centre.

4.4. Tocolysis

Where there is no evidence of infection, the gestation is <34 weeks and corticosteroids have not been completed, if contractions are occurring, tocolysis in order to complete the corticosteroids is reasonable. Refer to the guideline: [Preterm Labour - Management](#).

4.5. Continuing management

Delivery

- Where the gestation is > 36 weeks at presentation, induction of labour (if there are no contraindications to vaginal delivery) should be commenced at the next convenient opportunity (Refer to the procedure [Rupture of Membranes at Term – Pre-Labour Midwifery Assessment and Management](#)).
- If the woman is **GBS positive**, consideration should be given to prompt induction of labour from 32 weeks.
- In women who are being managed conservatively (see below), delivery should be effected if there is evidence of intrauterine infection, or when the gestation reaches 36 weeks.

4.5.1 Antibiotics

Antibiotic regimens

Refer to section 4.6 for further information.

The optimal regimen for prophylaxis for PPRM is uncertain. However, a suitable regimen is:

Erythromycin 250mg oral every 6 hours for 7 days PLUS amoxicillin 2g IV every 6 hours for 48 hours followed by amoxicillin 250mg oral every 8 hours for 5 days.

For patients hypersensitive to penicillin, give erythromycin 250 mg orally every 6 hours for 10 days.

Rupture of the Membranes - Preterm Premature (PPROM)

4.5.2 Surveillance for infection, growth

- clinical observations
 - 4/24 temperature, pulse
 - assessment of pv loss
 - assessment of abdominal pain or tenderness
- FBE weekly
- CTG twice per week
- Weekly assessment of fundal height
- Formal ultrasound examination initially, then every fortnight.

4.5.3 Outpatient management

- All women should be observed in hospital for 72 hours. If they remain well and are not in labour, they can then be discharged for outpatient management. The woman would be instructed to take her temperature t.d.s., observe PV Loss and be aware of fetal movements - returning if there are reduced fetal movements felt. They should be seen once each week in the PDCC and once each week in the antenatal clinic (complex care) with the above surveillance performed at each visit.
- Women who are referred to the hospital as in-utero transfers can be transferred back to the referring hospital at 34 weeks.

Sandringham campus:

- Women should attend the Birth Centre twice a week to be reviewed by the registrar.
- The surveillance outlined previously should be performed at each visit.

4.6 Educational Notes:

Infections are more commonly polymicrobial. Aggressive antibiotic treatment is *not* associated with increased rates of necrotizing enterocolitis or stillbirth.

Antibiotic treatment after PPRM reduces the risk of ascending infection, chorioamnionitis and delivery within 7 days. For the neonate, maternal antibiotics reduce major cerebral abnormalities, neonatal infections and the duration of neonatal intensive care unit admission.

Women presenting with PPRM should be screened for urinary tract infections, sexually transmitted infections, and group B streptococcus carriage, and treated with appropriate antibiotics if positive.

Indications for antibiotics in PPRM

PPROM may occur as a consequence of infection and is also associated with an increased risk of premature labour due to ascending infection. Therefore, antibiotics should be used for pregnancies where pregnancy prolongation is likely to result in a reduction of newborn morbidities.

For PPRM with suspected or confirmed chorioamnionitis (i.e. fever with other clinical manifestations such as uterine tenderness and purulent amniotic fluid), treat as for chorioamnionitis.

For PPRM without suspected or confirmed chorioamnionitis

- At or below 36 weeks gestation, give PPRM prophylaxis
- Imminent delivery or more than 36 weeks gestation, PPRM prophylaxis is not required

If labour starts during or after the completion of PPRM prophylaxis, give intrapartum prophylaxis for GBS carriers and those delivering before culture results are available. Refer to the guideline [GBS Colonisation Antenatal Intrapartum Strategies to Prevent Early - Onset Neonatal Sepsis](#).

Rupture of the Membranes - Preterm Premature (PPROM)

If the patient is undergoing caesarean section, surgical prophylaxis is also required. Refer to the guideline [Surgical Antibiotic Prophylaxis Guideline](#).

Special circumstances

PPROM remote from term

PPROM at <22 weeks poses special problems. The survival rate in these fetuses is about 20%. While the latency period is usually increased, the fetus is at risk of pulmonary hypoplasia. There is no reliable method for predicting this outcome. Immediate delivery is a reasonable option to discuss in these circumstances at consultant level.

5. Evaluation, monitoring and reporting of compliance to this guideline

Intermittent auditing of PPRM prophylaxis and management compliance with feedback to Obstetrics and Quality and Safety Unit.
